

How many channels does a spectrometer have

Overview

Optical detectors used in spectroscopic instruments are often classified as either single-channel detectors (SCDs) or multichannel detectors (MCDs). Single-channel detectors have one active sensing element that acts as single transducer. The integral-field spectrometer covers the wavelength range from $51\mu\text{m}$ to $220\mu\text{m}$, in two channels that operate simultaneously in the blue ($51\text{-}105\mu\text{m}$) and red ($102\text{-}220\mu\text{m}$) band. It provides a resolving power between 1000 and 4000 (i. a spectral resolution of $\sim 75\text{-}300\text{km/s}$) depending on wavelength, for a. These spectrometers utilize the phenomenon of optical dispersion. The light from a source can consist of a continuous spectrum, an emission spectrum (bright lines), or an absorption spectrum (dark lines).
